

# Why was the March 16-17 2008 Polar low poorly predicted?

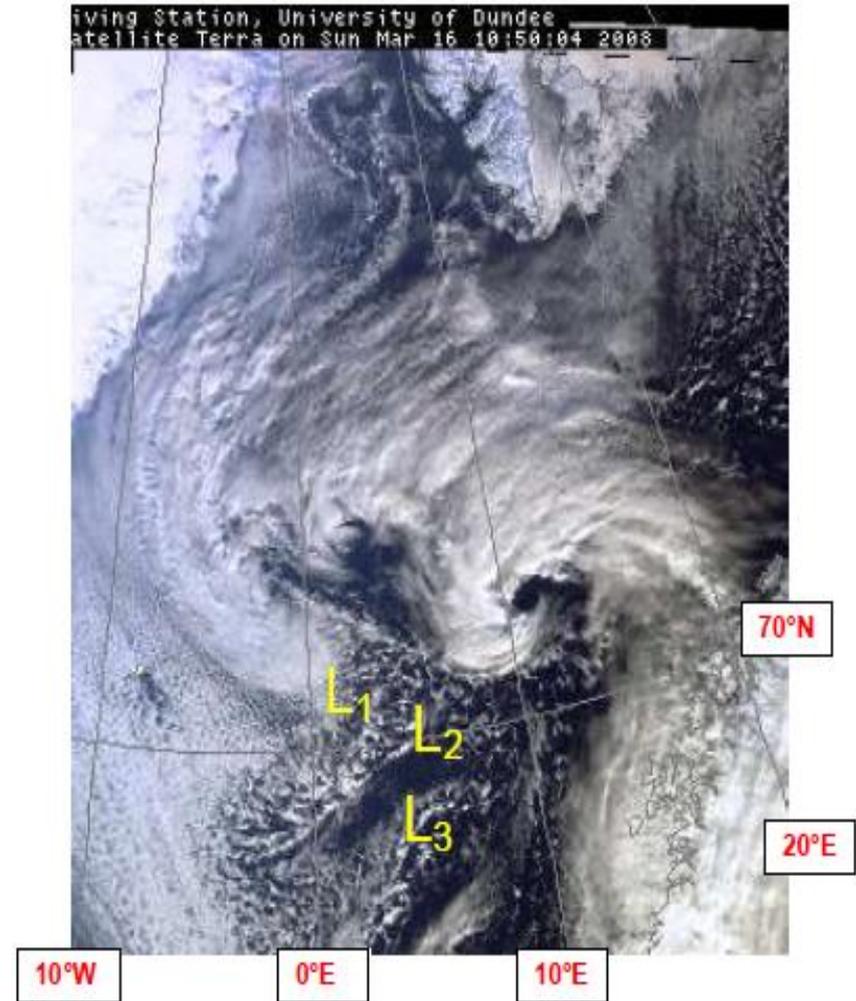

Bjørg Jenny Kokkvoll Engdahl, UiO  
Jón Egill Kristjánsson, UiO  
Thomas Spengler, UiB

NOAA-16 (SAF\_NE)day\_night 1508 UTC March 16 2008

# The March 16-17 polar low

- Occurred at the end of the IPY-THORPEX Andøya field campaign.
- Developed rapidly during the night of March 15-16.
- Poorly forecasted by the operational models.
- Made landfall at the coast of Trøndelag (63.5N, 10E), around 1200 UTC on March 17.

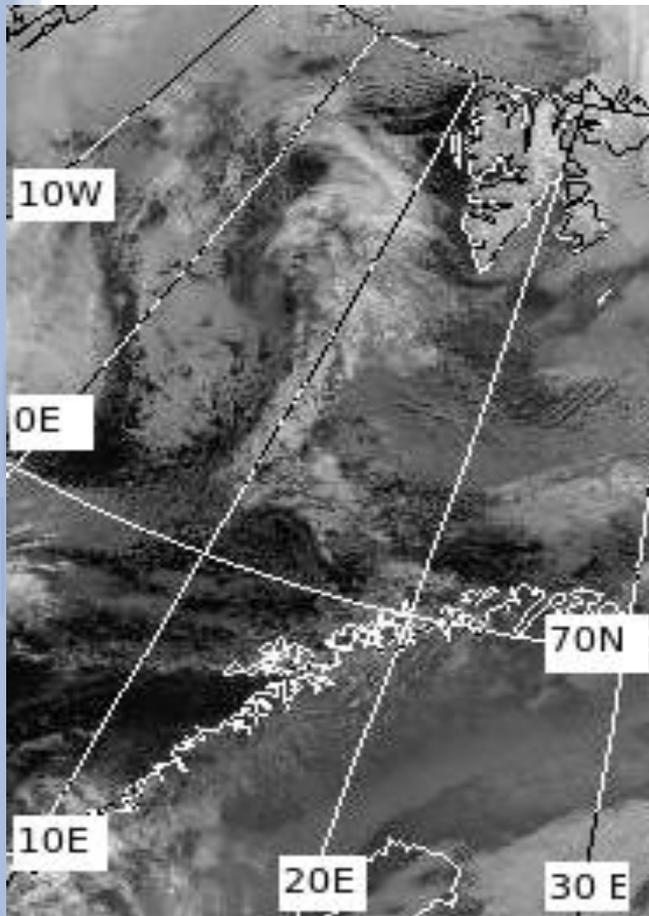

From Kristjánsson et al. (2011): BAMS

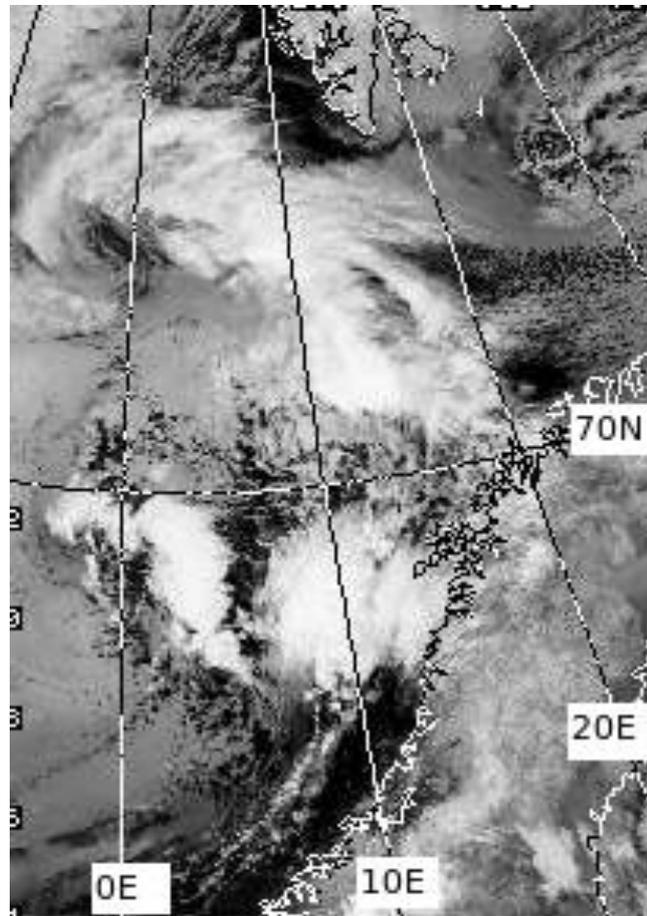

# Methodology

- Analyse the weather conditions prior to and during cyclogenesis
- Discuss possible trigger, propagation and forcing mechanisms
- Use the Weather Research and Forecasting (WRF) model to simulate the low: Perform several sensitivity experiments considering the importance of initial times, resolution and different parametrization options for physics, as well as the role of latent heating and contribution from surface fluxes.

# Conclusions

- Polar low development involved multiple vortices aligned along a low-level absolute vorticity streak
- Convection aligned with high low-level temperatures
- Energy propagation along upper-level PV-gradient?
- Simulations starting after 06 UTC 15 March systematically better than those with longer lead time:
  - ⇒ Due to dropsondes on 15 March?
- The WRF simulations showed that:
  - Initial conditions, in-cloud latent heating and contribution from surface fluxes are crucial
  - Higher resolution did not improve the results
